**(54) Title:** ELECTROPHORETIC DISPLAY PANEL WITH INTERNAL MESH BACKGROUND SCREEN**(57) Abstract**

A triode type electrophoretic display (10) includes a pair of substantially identical glass faceplates (12, 14) sealed to a pair of interstitial spacers (16a, 16b) to form a fluid-tight envelope for containing an electrophoretic fluid. An anodized black screen or mesh element (28) is sandwiched between the spacers and is opaque when viewed by the naked eye, thereby providing enhanced background coloration and contrast with pigment particles suspended in the fluid. The mesh (28) occupies an intermediate position relative to the extreme limits of travel of the particles as controlled by grid (18) and cathode (20) deposited upon one faceplate (14) on one side and the anode (26) deposited upon the other faceplate (12) on the other side. The screen (28) is porous, permits particles to pass through it, and is biased electrically to assist in moving the particles during formation of a displayed image.

DescriptionElectrophoretic Display Panel  
With Internal Mesh Background Screen5     Technical Field

          The present invention relates to an electrophoretic display panel apparatus and, more particularly, to triode and tetrode-type electrophoretic display panels having an internal mesh screen which enhances display operation.

10

Background Art

          Electrophoretic displays (EPIDS) are now well known. A variety of display types and features are taught in several patents issued in the names of the inventors herein, Frank J. DiSanto and Denis A. Krusos and assigned to the assignee herein, Copytele, Inc. of Huntington Station, New York. For example, U.S Patent Nos. 4,655,897 and 4,732,830, each entitled ELECTROPHORETIC DISPLAY PANELS AND ASSOCIATED METHODS describe the basic operation and construction of an electrophoretic display. U.S. Patent No. 4,742,345, entitled ELECTROPHORETIC DISPLAY PANELS AND METHODS THEREFOR, describes a display having improved alignment and contrast. Many other patents regarding such displays are also assigned to Copytele, Inc. Two pending patent applications which may have some relevance to the present invention are Application No. 07/667,630 entitled ELECTROPHORETIC DISPLAY PANEL WITH PLURAL ELECTRICALLY INDEPENDENT ANODE ELEMENTS and Application No. 07/345,825 entitled DUAL ANODE FLAT PANEL ELECTROPHORETIC DISPLAY APPARATUS, each of which shall be described below.

20  
25  
30

          The display panels shown in the above-mentioned patents operate upon the same basic principle, viz., if a suspension of electrically charged pigment

35

-2-

particles in a dielectric fluid is subjected to an applied electrostatic field, the pigment particles will migrate through the fluid in response to the electrostatic field. Given a substantially homogeneous suspension of particles having a pigment color different from that of the dielectric fluid, if the applied electrostatic field is localized it will cause a visually observable localized pigment particle migration. The localized pigment particle migration results either in a localized area of concentration or rarefaction of particles depending upon the sign and direction of the electrostatic field and the charge on the pigment particles. The electrophoretic display apparatus taught in the foregoing U.S. Patents are "triode-type" displays having a plurality of independent, parallel, cathode row conductors or lines deposited on one surface of a glass viewing screen. A layer of insulating photoresist material deposited over the cathode lines and photoetched down to the cathode lines to yield a plurality of insulator strips positioned transverse to the cathode lines, forms the substrate for a plurality of independent, parallel column or grid conductor lines. The resultant cathode and grid lines form an X-Y matrix for addressing the display and the columns and rows are arranged respectively in the horizontal and vertical directions or vice versa.

A glass cap member forms a fluid-tight seal with the viewing window along the cap's peripheral edge for containing the fluid suspension and also acts as a substrate for an anode plate deposited on the interior flat surface of the cap. When the cap is in place, the anode surface is in spaced parallel relation to both the cathode and the grid matrix. Given a

-3-

specific particulate suspension, the sign of the electrostatic charge which will attract and repel the pigment particles will be known. The cathode voltage, the anode voltage, and the grid voltage can then be ascertained such that when a particular voltage is applied to the cathode and another voltage is applied to the grid, the area proximate their intersection will assume a net charge sufficient to attract or repel pigment particles in suspension in the dielectric fluid. Since numerous cathode and grid lines are employed, there are numerous discrete intersection points which can be controlled by varying the voltage on the cathode and grid lines to cause localized visible regions of pigment concentration and rarefaction. Essentially then, the operating voltages on both cathode and grid must be able to assume at least two states corresponding to a logical one and a logical zero. Logical one for the cathode may either correspond to attraction or repulsion of pigment. Typically, the cathode and grid voltages are selected such that only when both are a logical one at a particular intersection point, will a sufficient electrostatic field be present at the intersection relative to the anode to cause the writing of a visual bit of information on the display through migration of pigment particles. The bit may be erased, e.g., upon a reversal of polarity and a logical zero-zero state occurring at the intersection coordinated with an erase voltage gradient between anode and cathode. In this manner, digitized data can be displayed on the electrophoretic display.

-4-

An alternative EPID construction is disclosed in Application Serial No. 07/667,630, referred to above, which relates to an electrophoretic display in which the previously described grid of electrically independently controllable elements or lines is replaced with a monolithic or electrically continuous grid. Further, the monolithic anode is replaced with a plurality of discrete, electrically independent elements. In displays constructed in accordance with the teachings of the aforesaid application, pixel writing and erasure is accomplished by impressing a voltage gradient between a selected anode element and a selected intersecting cathode line such that at their point of intersection, the gradient is sufficient to overcome a constant barrier voltage on the monolithic grid element causing migration of pigment particles past the grid.

A further alternative EPID construction is described in Application No. 07/345,825, referred to above, which relates to an electrophoretic display in which the cathode/grid matrix as is found in triode-type displays is overlaid by a plurality of independent separately addressable "local" anode lines. The local anode lines are deposited upon and align with the grid lines and are insulated therefrom by interstitial lines of photoresist. The local anode lines are in addition to a "remote" anode, which is a layer deposited upon the anode faceplate as in triode displays. The dual anode structure aforesaid provides enhanced operation by eliminating unwanted variations in display brightness between frames, increasing the speed of the display and decreasing the anode voltage

-5-

required during Write and Hold cycles, all as explained in Application No. 07/345,825, which is incorporated herein by reference.

5 To be useful as a display, an electrophoretic display must be able to assume a blank or erased state; must be able to display character data written during a Write operation; and must be able to  
10 continually maintain or hold the written characters (and blank characters) in a Hold mode until they are erased or overwritten. These three modes of operation, i.e., Erase, Write and Hold, are well documented in existing patents issued to the inventors herein and such description shall not be repeated at length herein.

15 One aspect of visual displays of all kinds which is a constant object of improvement is the clarity or resolution of the display. Resolution is at least partially dependent upon the size and number of the pixels which comprise the image. Resolution is also a  
20 function of the number of lines per inch associated with the display as well as the number of pixels per line. As is known in monochromatic displays, data can be displayed using two colors, i.e., a foreground color (A) and a background color (B) which may be  
25 interchangeable or reversible. That is, in a first mode of operation, color (A) is selected as foreground and color (B) serves as the background color. In a second mode of operation, color (B) is used to represent foreground data and color (A) to represent  
30 the background. A frequently used color combination in an electrophoretic display is a yellow foreground against black/dark blue background, i.e., yellow pigment particles are suspended in a black/dark blue solution. In many instances, the solution is colored

-6-

by a black/dark blue dye dissolved in a solvent. In order to achieve a sharp color contrast between the light colored pigment particles and the dark solution, a high concentration of dye is normally required. A high concentration is required due to the transparency of EPID displays (absent the dye) and to the thickness of the display. Since the dark solution fills the EPID display and surrounds the light colored pigment particles, high dye concentrations diminish display brightness and contrast. That is, even when the pigment particles are in the display position, not all dye is excluded from in between the particles or from in between the particle agglomeration and the glass faceplate through which it is viewed.

It is therefore an object of the present invention to provide an electrophoretic display with increased brightness and contrast by substantially reducing the above-described unwanted dye effect.

#### Disclosure of the Invention

The problems and disadvantages associated with the image resolution and brightness of conventional electrophoretic displays using contrast dye in the electrophoretic fluid are overcome by the present invention which includes an electrophoretic display having a fluid-tight envelope with a portion thereof which is at least partially transparent. An electrophoretic fluid is contained within the envelope and has pigment particles suspended therein. The display has electronics for selectively positioning the particles within the envelope such that they form images which are visible to a viewer when viewed through the transparent portion. A screen or mesh is disposed within the envelope and divides an interior space in the envelope containing the fluid into a

-7-

front portion proximate the transparent portion of the envelope and a back portion distal to the transparent portion. The mesh is at least partially opaque when viewed through the transparent portion of the envelope and obscures the particles from being viewed through the transparent portion when the particles are in the back portion. The screen or mesh allows the particles to pass through the pores under the control of the electronics such that the particles can be viewed or obscured depending upon their position with respect to the screen.

#### Brief Description of the Drawings

FIG. 1 is an exploded perspective view of an electrophoretic display in accordance with an exemplary embodiment of the present invention.

FIG. 2 is a cross-sectional view of the electrophoretic display shown in FIG. 1 in the unexploded state, taken along section line II-II and looking in the direction of the arrows.

FIG. 3 is an exploded perspective view of an electrophoretic display in accordance with a second exemplary embodiment of the present invention.

FIG. 4 is a cross-sectional view of the electrophoretic display shown in FIG. 3 in the unexploded state, taken along section line IV-IV and looking in the direction of the arrows.

FIG. 5 is a schematic diagram showing the connection of the devices depicted in FIGS. 1 through 4 to a power supply as controlled by a controller.

#### Best Mode for Carrying Out The Invention

FIG. 1 shows an electrophoretic display 10 in accordance with the present invention. The display 10 has an anode faceplate 12 and a cathode faceplate 14 which are sealably affixed on either side of

-8-

interstitial spacers 16a and 16b to form a fluid tight envelope for containing dielectric/pigment particle suspension or electrophoretic fluid (not shown). The faceplates 12 and 14 are typically flat glass plates upon which are deposited conductor elements. The techniques, materials and dimensions used to form the conductor elements upon the faceplates and the methods for making EPIDS, in general, are shown in U.S. Patent Nos. 4,655,897, 4,732,830 and 4,742,345 which patents are incorporated herein by reference.

As depicted in FIG. 1, a plurality of independent, electrically conductive cathode elements or lines 18 (horizontal rows) are deposited upon the cathode faceplate 14 using conventional deposition and etching techniques. It is preferred that the cathode members 18 be composed of Indium Tin Oxide (ITO) as set forth in U.S. Patent No. 4,742,345. A plurality of independent grid conductor elements or lines 20 are superposed in the vertical over the cathode lines 18 and are insulated therefrom by an interstitial photoresist layer 22 (see FIG. 2). The terms horizontal and vertical are used in regard to the orientation shown in Figure 1, but can be interchanged. The grid lines 20 may be formed by coating the photoresist layer 22 with a metal, such as nickel, using sputtering techniques or the like, and then selectively masking and etching to yield the intersecting but insulated configuration shown in FIGS. 1 and 2. Each cathode and grid line 18, 20 terminates at one end in a contact pad 24 or is otherwise adapted to permit connection to display driver circuitry (not shown). An anode 26 is formed on an interior surface of the anode faceplate 12 by plating with a thin layer of conductor material, such

-9-

as, chrome. A novel mesh element or screen 28 is sandwiched between spacers 16a and 16b to provide at least a partial barrier to the passage of light through the EPID 10. The mesh 28 has a plurality of pores 29 through which pigment particles may pass so as not to obstruct the normal operation of the EPID. Coincidental to the light barrier function, the mesh itself is an optically significant element, i.e., it is readily visible to the naked eye. In a preferred form, the mesh is constructed in a manner so that it is maximally visible, but the pores in the mesh are not visible, i.e., it is preferred that the mesh appear as a flat planar object. This is achieved by making the mesh with the minimum pore size which does not critically impede pigment movement. A screen having suitable characteristics is commercially available from the Buckee Mears Co., viz., a perforated stainless steel mesh having an approximate thickness and pore size of 10 to 12 mils. The mesh has an open area ratio, i.e., the ratio of the sum of pore area to the total surface area on one surface of the screen, of approximately 40% to 50%. The mesh is blackened by an anodizing process. The significance of the mesh screen 28 is that it provides a solid visual background for the display of pixels and it permits a reduction of dye concentration to effect a desired background intensity. For example, if the mesh were used in an EPID utilizing black/dark blue solution and yellow pigment particles, it could be colored black on at least one side so that the blackened side would function as a black background to enhance the background intensity attributable to the solution. It has been observed that the above-described mesh screen provides such an effective

-10-

background that no dye is required. Even if a less effective mesh were used, the objective of increased contrast would be realized because dye concentration along with unwanted dye effects could be decreased.

5 The screen 28 also functions to prevent inadvertent backlighting due to the overall translucence of the EPID 10. Since the screen allows for the reduction or elimination of dye, the pigment particles are more readily visible when in the display position and

10 display brightness and contrast are increased. It should be observed that the screen 28 is positioned in the EPID 10 such that when the pigment is in the display position, it is on one side of the screen 28 and when it is in the fully written position it is on

15 the other side of the screen 28, obscured from view by the screen 28 and/or dye in the solution.

It is preferable to fabricate the screen 28 from a conductive material enabling the screen to carry an electric charge for the purpose of aiding in

20 controlling the movement of the pigment particles. By utilizing the screen 28 as an electrode, the effect of the screen 28 as a physical barrier is compensated for and permits it to act solely as a visual barrier.

To form an EPID 10 like that shown in FIG. 1, the parts may assembled in a stack and placed in an oven

25 for baking. The spacers 16a and 16b, in that case, would be coated on surfaces which contact adjacent elements with a material which would become plastic at baking temperatures, such as, epoxy. Upon baking, the

30 meltable material flows and the elements form a laminate upon cooling. Of course, other methods exist within the scope of the normally skilled artisan for assembling the elements of the EPID 10 shown, such as,

-11-

e.g., gluing. The lamination of the EPID elements forms an envelope for containing the dielectric fluid/pigment particle suspension.

5 The cathode and grid lines 18 and 20 of the electrophoretic display 10 can assume a variety of voltages during operation for controlling the display operations of erase, hold and write. A typical panel  
10 ~~has a large number of intersections, e.g., 2,200 X 1,700~~ or a total of 3,740,000 separately addressable intersection points. For ease of illustration, however, only a few cathode lines 18 and grid lines 20 are depicted. Similarly, the shape and proportions of the elements depicted are for purposes of illustration only. The dimensions of the respective elements have  
15 also been greatly enlarged for illustration and are not necessarily in proportion to an actual operational device. More illustrations of electrophoretic displays, their components and electrical circuitry can be seen by referring to U.S. Patents Nos.  
20 4,742,345 and 4,772,820, each being awarded to the inventors herein and which are incorporated by reference herein.

Certain details have been omitted from the device depicted, but are taught in prior patents. For  
25 example it has been determined that a  $\text{SiO}_2$  coating on certain of the conductor elements provides beneficial results. See Application No. 07/675,733. Similarly, conductor elements having a tined configuration provide enhanced resolution, see U.S. Patent No.  
30 4,742,345.

FIG. 2 shows the electrophoretic display of FIG. 1 assembled and in cross-section. The anode 26 in the embodiment shown, is a plate-like area of conductor material having a length and width essentially

-12-

matching that of the cathode/grid matrix, i.e., coextensive with the matrix, as is taught in the above referenced patents and applications of the present Applicant. The cathode elements 18, grid elements 20 and grid insulator strips 22 as are also like those shown in the foregoing patents, etc. Since all conductor elements are quite thin, they extend beneath the interstitial spacers 16a and 16b without special provision and at least one end thereof provide a terminal exterior to the envelope for connecting display driver circuitry (not shown). For the purposes of illustration, epoxy bonding material 30 is depicted providing the laminating bond between spacers 16 and the faceplates 12 and 14 and for laminating the mesh screen 28 between the spacers 16a and b.

As stated above, the mesh screen 28 is preferably formed from a conductive material and is electrically biased to overcome any physical barrier it presents to particle migration. Exemplary voltages applied to the various elements in the EPID to perform certain basic functions are set forth below.

For the following operations, typical voltages would be:

+V1 = +200 (PULSED TO +400 DURING WRITING OF IMAGE)  
-V1 = -300  
+V2 = +140  
-V2 = -200  
V<sub>G</sub> HIGH = 0 (PULSED TO +3.0 DURING WRITING OF IMAGE)  
V<sub>G</sub> LOW = -10  
VAC = 100 V RMS  
V<sub>K</sub> HIGH = +15 (PULSED TO +18 DURING WRITING OF IMAGE)  
V<sub>K</sub> LOW = 0

-13-

## FULL WRITE:

V ANODE = +V1  
V MESH = VAC  
5 V GRID =  $V_G$  HIGH  
V CATH =  $V_K$  LOW

## ERASE:

V ANODE = -V1  
10 V MESH = -V2  
V GRID =  $V_G$  HIGH  
V CATH =  $V_K$  LOW

## HOLD:

15 V ANODE = +V1  
V MESH = +V2  
V GRID =  $V_G$  LOW  
V CATH =  $V_K$  HIGH

## 20 PREPARE FOR SELECTIVE IMAGE WRITING:

Set V MESH = VAC for 2 seconds, then return  
V MESH = +V2

## TO WRITE AN IMAGE:

25 V ANODE = +V1  
V MESH = pulsed from +V2 to +V1 (+400)

The image is then written in the usual manner by loading data into the grid elements and sequentially making each cathode low.

30

-14-

TO HOLD WRITTEN IMAGE

5       V ANODE = +V1  
      V MESH = VAC  
      V GRID =  $V_G$  LOW  
      V CATH =  $V_K$  HIGH  
      After 2 seconds return V MESH = +V2

TO REMOVE POWER FROM THE DISPLAY WITHOUT DISTURBING  
THE IMAGE:

10       V ANODE = +V1  
      V MESH = -V1  
      V GRID =  $V_G$  HIGH  
      V CATH =  $V_K$  LOW

15       Power is then removed from the anode, grid,  
      cathode and mesh in that order. The display is thus  
      completely removed from power, but the image displayed  
      remains undisturbed.

20       By writing with AC on the mesh and a positive  
      voltage on the anode, all pigment has been removed  
      from the front surface and only the black mesh is  
      visible. Thus, even in a suspension which is  
      completely devoid of dye, the black background is very  
      black and the pigment appears much brighter, improving  
      contrast and permitting the panel to be operated at a  
25       lower illumination.

30       FIGS 3 and 4 illustrate the incorporation of the  
      above-described mesh screen 28 into a tetrode-type  
      display. As can be readily determined by comparing  
      FIGS 1 and 2 to FIGS 3 and 4, many of the basic  
      elements of the display 10 are similar or the same in  
      both triode and tetrode-type displays. The same  
      reference numerals identifying similar elements shared  
      by both embodiments are employed to point out this

-15-

similarity. The embodiment shown in FIGS 3 and 4 differs from that previously described with respect to the addition of a plurality of local anode elements 32 which are deposited upon corresponding photoresist insulator strips 34 (see FIG. 4) formed upon the grid elements 20. The methods for forming the local anode elements 32 are set forth at length in Application No. 07/345,825. In brief, a layer of photoresist is applied over the grid elements 20, which are formed from a first metal, such as, chrome. A layer of a second metal, e.g., nickel or aluminum, is applied over the photoresist layer. Yet another layer of photoresist is applied over the second metal layer, and is then masked, exposed and developed in the same form as the grid elements. The second metal layer is then etched with a suitable solution. The photoresist between the first and second metal layers is then plasma etched. A layer of  $\text{SiO}_2$  is then deposited over the resulting structure.

As in the triode-type display, the screen 28 is preferably constructed from a conductor material and is electrically biased to assist in pigment particle position control. The following are exemplary voltages applied to the aforesaid elements to effect certain basic display operations.

For the following operations, typical voltages would be:

+V1 = +200 (PULSED TO +400 DURING WRITING OF IMAGE)  
-V1 = -300  
+V2 = +140  
-V2 = -200  
 $V_G$  HIGH = 0 (PULSED TO +3.0 DURING WRITING OF IMAGE)

-16-

$V_G$  LOW = -10  
 $V_K$  HIGH = +15 (PULSED TO +18 DURING WRITING OF IMAGE)  
 $V_K$  LOW = 0  
VLAH = +20 (PULSED TO +32 DURING WRITING OF IMAGE)  
5  $V_3$  = +20 (PULSED TO +32 DURING WRITING OF IMAGE)  
VAC = 100 V RMS  
(ANODE = REMOTE ANODE; L.A. = LOCAL ANODE)

## FULL WRITE:

10 V ANODE = +V1  
V MESH = VAC  
V L.A. = 0  
V GRID =  $V_G$  HIGH  
V CATH =  $V_K$  LOW

15

## ERASE:

V ANODE = -V1  
V MESH = +V3  
V L.A. = 0  
20 V GRID =  $V_G$  HIGH  
V CATH =  $V_K$  LOW

## HOLD:

V ANODE = +V1  
25 V MESH = +V2  
V L.A. = 0  
V GRID =  $V_G$  LOW  
V CATH =  $V_K$  HIGH

## 30 PREPARE FOR SELECTIVE IMAGE WRITING:

Connect MESH to VAC for 2 seconds

Return MESH to +V2

Connect REMOTE ANODE and MESH to LOCAL ANODE

V ANODE = VLAH

-17-

V MESH = VLAH  
V L.A. = VLAH  
V GRID =  $V_G$  LOW  
V CATH =  $V_K$  HIGH

5

## TO WRITE IMAGE:

The image is written in the usual manner by ~~loading data into the grid elements and sequentially~~ making each cathode low.

10

## HOLD IMAGE:

After writing the image, set the voltages as follows:

15 V ANODE = VLAH  
V MESH = VLAH  
V L.A. = VLAH  
V GRID =  $V_G$  LOW  
V CATH =  $V_K$  HIGH

## 20 HOLD IMAGE WITHOUT POWER:

To completely remove power from the panel without losing the image, proceed as follows:

25 V ANODE = +V1  
V MESH = +V2  
V L.A. = 0  
V GRID =  $V_G$  LOW  
V CATH =  $V_K$  HIGH  
V MESH = VAC FOR 2 SECONDS  
V MESH = RETURN TO -V1  
30 REMOVE VOLTAGE FROM ANODE, GRID, CATHODE AND MESH

## HOLD IMAGE WITHOUT POWER ALTERNATE:

An alternate method for removing power from the panel without losing the image is:

-18-

V ANODE = VLAH  
V MESH = -V2  
V L.A. = VLAH  
5 V GRID = V<sub>G</sub> LOW  
V CATH = V<sub>K</sub> HIGH  
Remove voltage from ANODE, LOCAL ANODE, GRID,  
CATHODE, and finally MESH.

10 By connecting the mesh to AC in the HOLD state  
and pulsing the positive anode, all excess goes  
through the mesh holes to the anode and after writing  
to the local anode, in the areas where pigment has  
been removed from the front surface, only the black  
mesh screen is visible. Thus, the suspension does not  
15 contain dye and the pigment brightness is greatly  
enhanced. Since the black is very dark and the  
pigment is brighter, the contrast is better and the  
panel may be viewed at lower illumination.

FIG. 5 illustrates in schematic form how the  
20 various components of the electrophoretic displays  
described above in reference to FIGS 1 through 4  
might be electrically connected to a suitable power  
supply 36 under the control of a digital controller 38  
in order to assume the correct voltage states during  
25 the operations described.

It should be understood that the embodiments  
described herein are merely exemplary and that a  
person skilled in the art may make many variations and  
modifications without departing from the spirit and  
30 scope of the invention as defined in the appended  
claims.

-19-

Claims

1. An electrophoretic display comprising:

(a) a fluid-tight envelope having a portion thereof which is at least partially transparent;

5 (b) an electrophoretic fluid contained within said envelope, said fluid having pigment particles suspended therein;

(c) means for selectively positioning said particles within said envelope such that said  
10 particles form images which are visible to a viewer when viewed through said transparent portion; and

(d) a mesh disposed within said envelope dividing an interior space in said envelope containing said fluid into a front portion proximate said transparent  
15 portion of said envelope and a back portion distal to said transparent portion, said mesh being at least partially opaque when viewed through said transparent portion of said envelope and obscuring said particles from being viewed through said transparent portion  
20 when said particles are in said back portion, said mesh allowing said particles to pass through under the control of said positioning means such that said particles can be viewed or obscured depending upon the position of said particles with respect to said mesh.

25 2. The display of Claim 1, wherein said pigment particles have a color which is differentiable from that of said fluid and from that of said screen.

30 3. The display of Claim 2, wherein said mesh is composed of an electrically conductive material and is selectively electrically chargeable to induce movement of said particles within said fluid in cooperation with said positioning means.

-20-

4. The display of Claim 3, wherein the open area ratio for said mesh is approximately from 40% to 50%.

5        5. The display of Claim 4, wherein said mesh is black in color.

6. The display of Claim 5, wherein said fluid is at least partially transparent.

7. The display of Claim 6, wherein said mesh is anodized.

10       8. The display of Claim 7, wherein said pigment particles are yellow.

9. The display of Claim 8, wherein said display has a first operating mode in which said pigment particles represent the foreground component of a displayed monochrome image and said mesh represents the background component of said displayed image and a second operating mode in which said pigment particles represent the background component of said displayed monochrome image and said mesh represents the foreground component of said displayed image.

20       10. The display of Claim 9, wherein said display is a triode-type display having an anode disposed proximate said transparent portion and a cathode and a grid disposed in said back portion and said positioning means includes said cathode, said grid and said anode.

11. The display of Claim 10, wherein said transparent portion of said envelope includes a portion through which said back portion can be viewed.

30       12. The display of Claim 9, wherein said display is a tetrode-type display having a remote anode disposed proximate said transparent portion, a cathode, a grid and a local anode disposed in said

-21-

back portion and said positioning means includes said cathode, said grid, said remote anode and said local anode.

5        13. The display of Claim 12, wherein said transparent portion of said envelope includes a portion through which said back portion can be viewed.

14. An electrophoretic display comprising:

~~(a) a fluid-tight envelope having a portion~~  
thereof which is at least partially transparent;

10        (b) an electrophoretic fluid contained within said envelope, said fluid having pigmented\* particles suspended therein;

15        (c) a plurality of elongated substantially parallel horizontal conductor members disposed within a first plane and at least partially contained within said envelope;

20        (d) a plurality of elongated substantially parallel vertical conductor members at least partially contained within said envelope electrically insulated from said horizontal members and disposed within a second plane, said first and said second planes being substantially parallel and in proximity to each other, said plurality of horizontal members and said plurality of vertical members forming a matrix with a  
25        plurality of intersections when viewed along a line perpendicular to said first and said second planes;

30        (e) a substantially planar conductor member disposed within a third plane proximate and substantially parallel to said second plane and at least partially contained within said envelope; and

(f) a perforated screen disposed between said vertical members and said planar member, said screen allowing said pigment particles to pass through the perforations thereof and being at least partially

-22-

opaque when viewed through said transparent portion of said envelope, each of said vertical and said horizontal members in said matrix being selectively electrically chargeable to induce movement of said particles within said fluid, said particles being visible through said transparent portion of said envelope.

15           15. The display of Claim 14, wherein said screen is substantially coextensive with said horizontal members and with said vertical members and has a color contrasting with that of said pigment particles.

10           16. The display of Claim 15, wherein said screen is composed of an electrically conductive material and is electrically insulated from said vertical and planar members.

15           17. The display of Claim 16, wherein said screen is selectively electrically chargeable to induce movement of said particles within said fluid in cooperation with said selectively electrically chargeable horizontal and vertical members.

20           18. The display of Claim 17, wherein said fluid is substantially transparent.

25           19. The display of Claim 18, wherein said envelope includes a first flat faceplate, a central portion of which is said transparent portion of said envelope, said first faceplate being a substrate for supporting said planar member.

30           20. The display of Claim 19, wherein said envelope includes a second substantially flat faceplate and at least one spacer interposed between and sealably attached to said first and second faceplates to form said envelope, said first plurality of horizontal conductor members being positioned proximate said second faceplate.

-23-

21. The display of Claim 20, wherein said at least one spacer includes two spacers, a first sealably affixed to said first faceplate and a second sealably affixed to said second faceplate, said first and second spacers sealably affixing to each other distal to said first and second faceplates and sandwiching said screen therebetween.

22. ~~The display of Claim 21, wherein the open area ratio for said screen is approximately from 40% to 50%.~~

23. The display of Claim 22, wherein said second faceplate is a substrate for supporting said first plurality of horizontal conductor members.

24. The display of Claim 23, wherein said second faceplate is at least partially transparent and said electrophoretic fluid is visible therethrough, said display being in its entirety at least partially translucent in a direction perpendicular to said first and second faceplates.

25. The display of Claim 24, wherein said screen reduces the translucence of said display.

26. The display of Claim 25, wherein said screen is black in color.

27. The display of Claim 26, wherein said screen is anodized.

28. The display of Claim 27, wherein said pigment particles are yellow.

29. The display of Claim 18, wherein said display has a first operating mode in which said pigment particles represent the foreground component of a displayed monochrome image and said screen represents the background component of said displayed image and a second operating mode in which said pigment particles represent the background component

-24-

of said displayed monochrome image and said screen represents the foreground component of said displayed image.

5       30. The display of Claim 18, wherein a dye of approximately the same color as said screen is added to said fluid.

10       31. The display of Claim 23, wherein said display is a triode-type display, said plurality of horizontal members being the cathode, said plurality of vertical members being the grid and said planar member being the anode.

15       32. The display of Claim 23, wherein said display is a tetrode-type display, said plurality of horizontal members being the cathode, said plurality of vertical members being the grid and said planar member being the remote anode and further including a plurality of local anode elements deposited upon said grid elements in alignment therewith and insulated therefrom by interstitial insulator strips.

20       33. In an electrophoretic display of the type having a cathode matrix comprising a plurality of parallel lines arranged in a given direction, with a grid matrix insulated from said cathode matrix and comprising a plurality of parallel lines each perpendicular to said cathode lines to form an X-Y addressing matrix with a conventional anode electrode separated from said X-Y matrix with the space between said anode electrode and said X-Y matrix accommodating an electrophoretic dispersion including pigment particles suspended in a fluid, the improvement therewith of:

25

30

-25-

5 a mesh disposed within said space between said anode electrode and said X-Y matrix, said mesh allowing said pigment particles to pass therethrough under the control of said anode and said X-Y matrix, said mesh being at least partially opaque and providing a contrasting background for said pigment particles.

10 ~~34. The device of Claim 33, wherein said mesh is perforated by a plurality of perforations through which said particles pass, said mesh when interposed between a viewer and said pigment particles at least partially obscuring said pigment particles from view.~~

15 35. The device of Claim 34, wherein said pigment particles have a color which is differentiable from that of said fluid and from that of said mesh.

20 36. The device of Claim 35, wherein said screen is composed of an electrically conductive material and is selectively electrically chargeable to induce movement of said particles within said fluid in cooperation with said X-Y matrix and said anode.

37. The device of Claim 36, wherein the open area ratio for said mesh is approximately from 40% to 50%.

25 38. The device of Claim 37, wherein said mesh is black in color.

39. The device of Claim 38, wherein said fluid is at least partially transparent.

40. The device of Claim 39, wherein said mesh is anodized.

30 41. The device of Claim 40, wherein said pigment particles are yellow.

-26-

42. The device of Claim 41, wherein said display has a first operating mode in which said pigment particles represent the foreground component of a displayed monochrome image and said screen represents the background component of said displayed image and a second operating mode in which said pigment particles represent the background component of said displayed monochrome image and said mesh represents the foreground component of said displayed image.

43. The device of Claim 42, wherein said display further includes an additional anode electrode comprising a plurality of parallel lines each associated with and insulated from a respective grid line with said additional anode operative to control the path of said pigment particles to and from said X-Y matrix and through said mesh and to allow excess pigment to remain at said conventional anode electrode.

44. A method for operating an electrophoretic display of the type having a cathode matrix comprising a plurality of parallel lines arranged in a given direction, with a grid matrix insulated from said cathode matrix and comprising a plurality of parallel lines each perpendicular to said cathode lines to form an X-Y addressing matrix with a conventional anode electrode separated from said X-Y matrix with the space between said anode electrode and said X-Y matrix accommodating an electrophoretic dispersion including pigment particles suspended in a fluid, and a screen composed of an electrically conductive material disposed within said space between said anode electrode and said X-Y matrix, said screen allowing said pigment particles to pass therethrough under the control of said anode and said X-Y matrix, said screen

-27-

being at least partially opaque and providing a contrasting background for said pigment particles includes the steps of;

5 (a) electrically connecting said cathode matrix, said grid matrix, said screen and said conventional anode to a source of electrical potential energy, said source providing a range of independent and selectively variable voltages to each of said cathode matrix, said grid matrix, said screen and said anode under the control of control means for controlling the voltage level supplied by said source to each of said cathode matrix, said grid matrix, said screen and said anode; and

10 (b) controlling said source of electrical potential energy with said control means such that voltage levels are applied to said cathode matrix, said grid matrix, said screen and said anode for performing display operations.

15 45. The method of Claim 44, wherein said display operations include placing said display in FULL WRITE mode by said source providing under the control of said control means approximate voltage levels of +200 v to said anode, 100 v rms AC to said screen, +1.5 to +3.0 v to said grid matrix and -10 v to said cathode matrix.

20 46. The method of Claim 44, wherein said display operations include placing said display in ERASE mode by said source providing under the control of said control means approximate voltage levels of -300 v to said anode, -200 v to said screen, +1.5 to +3.0 v to said grid matrix and -10 v to said cathode matrix.

-28-

47. The method of Claim 46, wherein said display operations include placing said display in ERASE-HOLD mode, after having placed said display in ERASE mode, by said source providing under the control of said control means approximate voltage levels of +200 v to said anode, +140 v to said screen, -10 v to said grid matrix and +1.5 to +3.0 v to said cathode matrix.

48. The method of Claim 47, wherein said display operations include writing an image on said display after said display is in ERASE-HOLD mode by said source providing under the control of said control means approximate voltage levels of 100 v rms AC to said screen for about 2 seconds then +140 v to said screen, +200 v to said anode, then pulsing the voltage on said screen from +140 to +400 while said image is written, and by loading image data into said grid elements and sequentially placing each cathode element at -10 v.

49. The method of Claim 48, wherein said display operations include placing said display in an IMAGE-HOLD mode wherein a written said image is held on said display by said source providing under the control of said control means approximate voltage levels of 100 v rms AC to said screen for about 2 seconds then +140 v to said screen, +200 v to said anode, -10 v to said grid matrix and +1.5 to 3.0 v to said cathode matrix.

50. The method of Claim 49, wherein said display operations include placing said display in a POWER-OFF-IMAGE-HOLD mode wherein a written said image is held on said display after the removal of power from said display, said POWER-OFF-IMAGE-HOLD mode being achieved by said source providing under the control of

-29-

said control means approximate voltage levels of +200 v to said anode, -300 v to said screen, +1.5 to 3.0 v to said grid matrix and -10 v to said cathode matrix.

51. The method of Claim 44, wherein said display  
5 further includes an additional anode electrode  
comprising a plurality of parallel lines each  
associated with and insulated from a respective grid  
line with said additional anode operative to control  
the path of said pigment particles to and from said X-  
10 Y matrix and through said screen and to allow excess  
pigment to remain at said conventional anode electrode  
and further comprising the step of electrically  
connecting said controlled source of electrical  
potential energy to said additional anode, voltage  
15 levels supplied to said additional anode being  
included in said step of controlling for performing  
display operations.

52. The method of Claim 51, wherein said display  
operations include placing said display in FULL WRITE  
20 mode by said source providing under the control of  
said control means approximate voltage levels of +200  
v to said conventional anode, 0 v to said additional  
anode, 100 v rms AC to said screen, +1.5 to +3.0 v to  
said grid matrix and -10 v to said cathode matrix.

53. The method of Claim 51, wherein said display  
operations include placing said display in ERASE mode  
by said source providing under the control of said  
control means approximate voltage levels of -300 v to  
said conventional anode, 0 v to said additional anode,  
25 +20 v to said screen, +1.5 to +3.0 v to said grid  
matrix and -10 v to said cathode matrix.

-30-

54. The method of Claim 53, wherein said display operations include placing said display in ERASE-HOLD mode after having placed said display in ERASE mode, by said source providing under the control of said control means approximate voltage levels of +200 v to  
5 said conventional anode, 0 v to said additional anode, +140 v to said screen, -10 v to said grid matrix and +1.5 to +3.0 v to said cathode matrix.

55. The method of Claim 54, wherein said display  
10 operations include writing an image on said display after said display is in ERASE-HOLD mode, by said source providing under the control of said control means approximate voltage levels of 100 v rms AC to  
15 said screen for about 2 seconds then +140 v to said screen, +200 v to said conventional anode after said conventional anode, said additional anode and said screen are electrically connected, and writing said  
20 image by loading image data into said grid elements and sequentially placing each cathode element at -10 v.

56. The method of Claim 55, wherein said display operations include placing said display in an IMAGE-HOLD mode wherein a written said image is held on said display by said source providing under the control of  
25 said control means approximate voltage levels of +200 v to said conventional anode, +200 v to said screen, +200 to said additional anode, -10 v to said grid matrix and +1.5 to 3.0 v to said cathode matrix.

57. The method of Claim 56, wherein said display  
30 operations include placing said display in a POWER-OFF-IMAGE-HOLD mode wherein a written said image is held on said display after the removal of power from said display, said POWER-OFF-IMAGE-HOLD mode being achieved by said source providing under the control of

-31-

5        said control means approximate voltage levels of +200 v to said conventional anode, +140 v to said screen, 0 v to said additional anode, -10 v to said grid matrix and +1.5 to 3.0 v to said cathode matrix, then 100 v rms to said screen for 2 seconds, -300 v to said screen, then disconnecting said source of electrical potential from said conventional anode, said additional anode, said grid matrix, said cathode matrix and said screen, in that order.

10        58. The method of Claim 56, wherein said display operations include placing said display in a POWER-OFF-IMAGE-HOLD mode wherein a written said image is held on said display after the removal of power from said display, said POWER-OFF-IMAGE-HOLD mode being  
15        achieved by said source providing under the control of said control means approximate voltage levels of +200 v to said conventional anode, -300 v to said screen, +200 v to said additional anode, -10 v to said grid matrix and +1.5 to 3.0 v to said cathode matrix, then  
20        disconnecting said source of electrical potential from said conventional anode, said additional anode, said grid matrix, said cathode matrix and said screen, in that order.
